$$

Parents of $Y:\{1,2\}$
Call coordinate $i$ detectable for coalition X if $\left|\left\{\mathrm{x}_{1, \mathrm{i}}, \mathrm{x}_{2, j}\right\}\right|>1$

## Marking assumption (Boneh-Shaw '98):

The pirates cannot change the contents of undetectable coordinates.

Objective of system designer: identify pirates exactly or with low error

## Fingerprinting

$\mathcal{M}=\{1,2, \ldots, \mathrm{M}\}$ - the set of users
$\mathrm{U} \subset \mathcal{M},|\mathrm{U}| \leq \mathrm{t}$ a coalition
Fingerprinting code:

$$
\begin{aligned}
\mathrm{f}_{\mathrm{k}}: \mathcal{M} \rightarrow \mathcal{Q}^{\mathrm{n}} \quad & \text { (assignment) } \\
\phi_{\mathrm{k}}: \mathcal{Q}^{\mathrm{n}} \rightarrow \mathcal{M} \cup\{0\} & \text { (identification) } \\
\mathrm{k} & \in \mathcal{K} \text { randomization } \mathrm{P}_{\mathrm{K}}(\mathrm{k})=\pi(\mathrm{k})
\end{aligned}
$$

Let $\mathrm{U}=\left\{\mathrm{u}_{1}, \ldots, \mathrm{u}_{\mathrm{t}}\right\}, \mathrm{f}_{\mathrm{k}}\left(\mathrm{u}_{\mathrm{i}}\right)=\mathrm{x}_{\mathrm{i}}$

Collusion attack:
$\mathrm{V}\left(\mathrm{y} \mid \mathrm{x}_{1}, \ldots, \mathrm{x}_{\mathrm{t}}\right)>0$ only if y follows the marking assumption

## Fingerprinting capacity

Goal of system designer: maximize the number of supported users $M=q^{R n}$

## Error probability of identification:

$$
e(U, F, \Phi, V)=E_{K} \sum_{y: \phi_{K}(y) \notin U} V\left(y \mid f_{k}(U)\right)
$$

A randomized code $(F, \Phi)$ is $t$-fingerprinting with $\varepsilon$-error if

$$
\max _{V \in \mathcal{V}_{r}} \max _{U: \mid U \leq t} e(U, F, \Phi, V)<\varepsilon
$$

Rate $\mathrm{R} \geq 0$ is $\varepsilon$-achievable for t -secure fingerprinitng if for every $\delta>0$ and every (sufficiently large) $n$ there exists a $q$-ary code ( $F, \Phi$ ) of length $n$ with rate

$$
\begin{aligned}
& \quad(1 / n) \log _{q} \mathrm{M}>\mathrm{R}-\delta \\
& \mathrm{C}_{\mathrm{t}, \mathrm{q}}(\varepsilon)=\text { sup of } \varepsilon \text {-achievable rates }
\end{aligned}
$$

Capacity $\quad C_{t, q}=\lim _{\varepsilon \rightarrow 0} C_{t, q}(\varepsilon)$

## Fingerprinting capacity

A.B., G.R. Blakley, G. Kabatiansky (ISIT 2001) For any constant $t$

$$
\mathrm{C}_{\mathrm{t}, \mathrm{q}}>0, \varepsilon=\exp (-\Theta \mathrm{n})
$$

separating arrays, list decoding
G. Tardos (FOCS '03) $\mathrm{C}_{\mathrm{t}, \mathrm{a}} \geq \Omega\left(\mathrm{t}^{-2}\right)$ time-varying randomized encoding map
A.B., Prasanth A., I. Dumer (ISIT '07) lower bounds: $\quad C_{2,2} \geq 1 / 4 ; C_{3,2} \geq 1 / 12$;
upper bounds: $\quad \mathrm{C}_{2,2} \leq 0.322, \mathrm{C}_{3,2} \leq 0.199$

$$
\Omega\left(1 / t^{2}\right) \leq \mathrm{C}_{\mathrm{t}, 2} \leq \mathrm{O}(1 / \mathrm{t})
$$

## Fingerprinting capacity

A general upper bound (A.B., Prasanth A., I. Dumer ('07)):

$$
\begin{aligned}
& C_{t, q}(\epsilon) \leq \min _{V \in \mathcal{V}_{t}} \max _{P_{X_{1}, \ldots X_{t}}} \max _{1 \leq i \leq t} I\left(X_{i} ; Y \mid X_{1}^{i-1}, X_{i+1}^{t}\right) \\
& \text { where } X_{1}, \ldots, X_{t}, Y \text {-ary rv's } \\
& P_{Y \mid X_{1} \ldots X_{t}}=V \text { s.t. } X_{1}, \ldots, X_{t} \text { are independent. }
\end{aligned}
$$

E. Amiri and G. Tardos (SODA'09) computed the asymptotics of this bound:

$$
\mathrm{C}_{\mathrm{t}, 2}=\Theta\left(\mathrm{t}^{-2}\right)
$$

Y.-W. Huang and P. Moulin (ISIT'09): $1 /\left(2 \mathrm{t}^{2} \ln 2\right) \leq \mathrm{C}_{\mathrm{t}, 2} \leq 1 /\left(\mathrm{t}^{2} \ln 2\right)$ general results on fingerprinting capacity

Constructions of capacity-approaching fingerprinting codes

## Two-level fingerprinting

The set of users $\mathcal{M}=\mathcal{M}_{1} \times \mathcal{M}_{2}$ ( $M_{1}$ groups of $M_{2}$ users each)
Encoder $\mathrm{f}_{\mathrm{K}}: \mathcal{M}_{1} \times \mathcal{M}_{2} \rightarrow \mathcal{Q}^{\mathrm{n}}$
Tracing $\phi_{K}: \mathcal{Q}^{n} \rightarrow\left(\mathcal{M}_{1} \cup 0\right) \times\left(\mathcal{M}_{2} \cup 0\right)$
If coalition satisfies $|\mathrm{U}| \leq \mathrm{t}_{2}, \phi_{\mathrm{K}}(\mathrm{y}) \cap \mathrm{U} \neq \emptyset$
If $\mathrm{t}_{2}<\mathrm{t} \leq \mathrm{t}_{1}$, then $\phi_{\mathrm{K}}$ identifies correctly the group that contains some of the pirates

Existence of two-level fingerprinting codes such that
$\mathrm{M}_{1}=\mathrm{q}^{\mathrm{nR} 1}, \mathrm{M}_{2}=\mathrm{q}^{\mathrm{nR} 2}$,
$R_{1}>0, R_{2}>0$
Prasanth A., A.B. (ISIT2010)

$$
\begin{array}{lllllllllll}
\mathrm{K}_{1} & = & 1 & 3 & 5 & 0 & 7 & 9 & 8 & 2 & 8 \\
\mathrm{~K}_{2} & = & 1 & 2 & 5 & 9 & 1 & 9 & 8 & 2 & 5 \\
\mathrm{~K}_{3} & = & 4 & 5 & 6 & 0 & 4 & 9 & 8 & 7 & 5
\end{array}
$$

Unregistered Key

$$
Y \quad=1 ? 50 ? 9825
$$

$$
\begin{array}{llllllllll}
(1,2) & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
(1,3) & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
(2,3) & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{array}
$$

Parents of $Y$ : $\{1,2\}$ or $\{2,3\}$ or $\{1,3\}$ identification impossible

More broadly, the pirates may deviate from the marking assumption in a certain number of coordinates

To what extent can we relax the marking assumption?

## Parent identifying codes

C a subset of $\mathcal{Q}^{\mathrm{n}}$, where $\mathcal{Q}$ is a finite set of cardinality q (alphabet)
$\mathrm{U}=\left\{\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{\mathrm{t}}\right\} \subset \mathrm{C}$ - pirate coalition, a set of t pirates
$\mathrm{y}=\mathrm{f}(\mathrm{U}) \in \mathcal{Q}^{\mathrm{n}}$ - collusion attack
$\langle U\rangle$ - set of descendants of $U$ (with or without the marking assumption)
$\langle C\rangle_{t}=U\langle U\rangle$ - set of all possible attack vectors y $U \subset C,|U| \leq t$
Definition: C has a $\boldsymbol{t}$-IPP property if for all $\mathrm{y} \in\langle\mathrm{C}\rangle_{\mathrm{t}}$

$$
\bigcap_{U \subset C,|U| \leq t, y \in\langle U\rangle} U \neq \emptyset
$$

H.D.L.Hollmann, J.H.vanLint, J.-P.Linnartz, L.M.G.M.Tolhuizen, JCTA 1998, no. 2 (case t=2)

## Collusion attacks

$$
U=\left\{x_{1}, x_{2}, \ldots, x_{t}\right\}
$$

Narrow attack rule: $\quad y_{i} \in\left\{x_{1, i}, x_{2, i}, \ldots, x_{t, j}\right\}$
For narrow-sense attack, it is possible to construct large-size IPP codes if (and only if) $\mathrm{t} \leq \mathrm{q}-1$ (nonzero rate; exact identification)

A. B., G. Cohen, S. Encheva, G. Kabatiansky, G. Zémor,<br>SIAM J. Discrete Math, 14, 2001.

## Intermediate case

$U=\left\{x_{1}, x_{2}, \ldots, x_{t}\right\}$
$\mathrm{y}=\left(\mathrm{y}_{1}, \mathrm{y}_{2}, \ldots, \mathrm{y}_{\mathrm{n}}\right) \in \mathcal{Q}^{\mathrm{n}} \cup$ ? (erasure)
Narrow attack rule: $\quad y_{i} \in\left\{x_{1, i}, x_{2, i}, \ldots, x_{t, j}\right\}$

What happens for more powerful attacks? -
Suppose there are $\varepsilon$ n coordinates that deviate from the above rule while the remaining $(1-\varepsilon)$ n coordinates obey it

Call such en coordinates mutant
H.-J. Gutz and B. Pfitzmann, '99
T. Sirvent, '07
D. Boneh and M. Naor '08

O Bliiet and D. Phan '08.

## Problem statement

A ( $\mathrm{t}, \varepsilon$ )-IPP code (robust t-IPP code) $\mathrm{C} \subset \mathcal{Q}^{\text {n }}$ guarantees exact identification of at least one member of the pirate coalition $\mathrm{U},|\mathrm{U}| \leq \mathrm{t}$ for any collusion attack with at most $\varepsilon$ n mutations.

Define

$$
\begin{gathered}
R_{q}(n, t, \epsilon)=\max \left\{R(\mathcal{C}): \mathcal{C} \subset \mathcal{Q}^{n} \text { is }(t, \epsilon)-\mathrm{IPP}\right\} \\
R_{q}(t, \epsilon)=\liminf _{n \rightarrow \infty} R_{q}(n, t, \epsilon) .
\end{gathered}
$$

Find $\epsilon_{\text {crit }}=\epsilon_{\text {crit }}(q, t):=\sup \left(\epsilon: R_{q}(t, \epsilon)>0\right)$
Call coordinate $i$ detectable for coalition $U$ if $\left\{\left\{\mathrm{x}_{1, i}, \mathrm{x}_{2, i}, \ldots, \mathrm{x}_{\mathrm{t}, j}\right\} \mid \geq 2\right.$
(i) only detectable coordinates can mutate, always erasure:
(ii) only detectable coordinates can mutate:
$\epsilon_{\text {crit }}^{*, D}$
(iii) any coordinate can be erased
(iv) any coordinate can mutate to any letter in $\mathcal{Q}$ :
$\epsilon_{\text {crit }}^{D}$
$\epsilon_{\text {Crit }}^{*}$
$\epsilon_{\text {crit }}$

## Problem statement

A ( $\mathrm{t}, \varepsilon$ ) -IPP code (robust t-IPP code) $\mathrm{C} \subset \mathcal{Q}^{\mathrm{n}}$ guarantees exact identification of at least one member of the pirate coalition $\mathrm{U},|\mathrm{U}| \leq \mathrm{t}$ for any collusion attack with at most $\varepsilon$ n mutations.

Find

$$
\epsilon_{\mathrm{crit}}=\epsilon_{\mathrm{crit}}(q, t):=\sup \left(\epsilon: R_{q}(t, \epsilon)>0\right) .
$$

(i) only detectable coordinates can mutate, always erasure:

$$
\epsilon_{\mathrm{crit}}(q, t) \leq\left\{\begin{array}{c}
\epsilon_{\mathrm{crit}}^{*}(q, t) \\
\epsilon_{\mathrm{crit}}^{D}(q, t)
\end{array}\right\} \leq \epsilon_{\mathrm{crit}}^{*, D}(q, t)
$$

## Existence of robust IPP codes

$(\mathrm{t}, \varepsilon)$ Traceability Code: $(\mathrm{t}, \varepsilon)$-IPP code that permits pirate identification by the minimum Hamming distance to $y$

Proposition: For $q>\mathrm{t}^{2} /(1-\varepsilon(\mathrm{t}+1))$ there exist infinite sequences of $(\mathrm{t}, \varepsilon)$-TA codes with positive code rate.

Proof: Coalition $U=\left\{u^{1}, \ldots, u^{\mathrm{t}}\right\}, \mathrm{y} \in\langle\mathrm{U}\rangle_{\mathrm{t}}$

$$
\begin{aligned}
\sum_{u \in X} s_{H}(y, u) & \geq(1-\epsilon) n \\
s_{H}(y, c) & \leq n \epsilon+\sum_{u \in U} s_{H}(u, c) \leq n \epsilon+t(n-d) \\
& <(1-\epsilon) n t^{-1}
\end{aligned}
$$

This connects the Hamming distance to $\mathrm{q}, \varepsilon$.
Corollary: For $q>t^{2}, \varepsilon_{\text {crit }}(q, t) \geq 1 /(t+1)-t^{2} /(q(t+1))$
B. Chor, A. Fiat, M. Naor, Tracing traitors, Crypto'94

## Existence of robust IPP codes

Traceability yields existence of IPP codes for $q \geq t^{2}$
Theorem: $\varepsilon_{\text {crit }}(q, t)>0$ for $q \geq t+1$
Proof idea:
( $\mathrm{t}, \mathrm{u}$ )-hashing families, $\mathrm{u}=\left\lfloor(\mathrm{t} / 2+1)^{2}\right\rfloor$
$C \subset \mathcal{Q}^{n}$ is $(t, u)$-hash if $\forall T \subset U \subset C,|T|=t,|U|=u$

$$
\exists i: \forall \mathrm{x} \in \mathrm{~T}, \mathrm{y} \in \mathrm{U}, \mathrm{y} \neq \mathrm{x}: \quad \mathrm{x}_{\mathrm{i}} \neq \mathrm{y}_{\mathrm{i}}
$$

( $\mathrm{t}, \mathrm{u}$ )-hash distance $=\#$ hash coordinates $\geq 2 \mathrm{t}+1$

## Upper bounds for robust IPP codes

1. Hash codes. A code $C \subset \mathcal{Q}^{n}$ is called a hash code (s-PHF) if for any s codewords there is a hash coordinate, i.e., a coordinate that separates them: $\mathrm{x}_{1, i \neq \mathrm{x}_{2,1} \neq \ldots \neq \mathrm{x}_{\mathrm{s}, \mathrm{i}} \text {. }}$
For two s-subsets $U_{1}, U_{2}, U_{1} \cap \mathrm{U}_{2}=\emptyset$, the number of coordinates that separates them is called $s$-hash distance $\mathrm{d}_{\mathrm{s}}\left(\mathrm{U}_{1}, \mathrm{U}_{2}\right)$

## Proposition:

(L. A. Bassalygo, M.Burmester, A.G.Dyachkov, G.A.Kabatiansky, Hash codes ISIT'97)

Let $C$ be a code with $d_{s}(C)=d$

$$
\begin{gathered}
|\mathcal{C}| \leq\binom{ s}{2} \frac{d}{d-n \pi_{s, q}} \quad\left(d>n \pi_{s, q}\right) \\
\pi_{s, q} \triangleq \prod_{i=1}^{s-1}\left(1-i q^{-1}\right)
\end{gathered}
$$

## Upper bounds for robust IPP codes

1. Hash codes. A code $C \subset \mathcal{Q}^{n}$ is called a hash code (s-PHF) if for any s codewords there is a hash coordinate, i.e., a coordinate that separates them: $\mathrm{x}_{1,1,} \neq \mathrm{x}_{2,1} \neq \ldots \neq \mathrm{x}_{\mathrm{s}, \mathrm{i}}$.
For two s-subsets $U_{1}, U_{2}, U_{1} \cap U_{2}=\emptyset$, the number of coordinates that separates them is called s-hash distance $\mathrm{d}_{\mathrm{s}}\left(\mathrm{U}_{1}, \mathrm{U}_{2}\right)$
2. Upper bound

Theorem:

$$
\begin{array}{cc}
\epsilon_{\text {crit }}^{*, D}(q, t)<\pi_{t+1, q}, & \pi_{s, q} \triangleq \prod_{i=1}^{s-1}\left(1-i q^{-1}\right) \\
\epsilon_{\text {crit }}^{D}(q, t)<\pi_{t+1, q} /(t+1) &
\end{array}
$$

Proof idea: Let $C$ be a t-IPP code, and let $d_{t+1}$ be its hash distance
Take the $t+1$ codewords that realize $d_{t+1}$. Form

$$
y_{i}=? \text { if } i \text { is a hash coordinate }
$$

$$
y_{i}=\operatorname{maj}\left(x_{1, i}, \ldots, x_{t+1, i}\right) \text { otherwise }
$$

## Robust 2-IPP codes

In the case $\mathrm{t}=2$ we can find exact answers
Theorem: $\quad q \geq 3$ :

$$
\begin{gathered}
\epsilon_{\text {crit }}^{*, D}(q, 2)=\pi_{3, q} \triangleq\left(1-\frac{1}{q}\right)\left(1-\frac{2}{q}\right), \\
\epsilon_{\text {crit }}^{D}(q, 2)=1 / 3 \pi_{3, q} \\
\epsilon_{\text {crit }}^{*}(q, 2)=\delta_{2,2} \triangleq\left(1-q^{-1}\right)\left(1-3 q^{-1}+3 q^{-2}\right) \\
\epsilon_{\text {crit }}(q, 2)=1 / 3 \pi_{3, q}
\end{gathered}
$$

## 2-IPP codes

A code $C \subset \mathcal{Q}^{n}$ is (2,2)-separating if every $\left(x_{1}, x_{2}\right),\left(x_{3}, x_{4}\right) \in C x C$ are separated by some coordinate
$C$ is 3-hash if every $x_{1}, x_{2}, x_{3}$ are separated by a coordinate
Lemma (Hollmann et al. '98)
C is 2-IPP iff C is (2,2)-separating and 3-hash.

## Robust 2-IPP codes

## Exact answers are available

## Theorem:

$$
\begin{gathered}
\epsilon_{\text {crit }}^{*, D}(q, 2)=\pi_{3, q} \triangleq\left(1-\frac{1}{q}\right)\left(1-\frac{2}{q}\right) \\
\epsilon_{\text {crit }}^{D}(q, 2)=1 / 3 \pi_{3, q} \\
\epsilon_{\text {crit }}^{*}(q, 2)=\delta_{2,2} \triangleq\left(1-q^{-1}\right)\left(1-3 q^{-1}+3 q^{-2}\right) \\
\epsilon_{\text {crit }}(q, 2)=1 / 3 \pi_{3, q}
\end{gathered}
$$

Proof idea: C is $(2,2)$ separating if every distinct $\mathrm{x}_{1}, \mathrm{x}_{2}, \mathrm{x}_{3}, \mathrm{x}_{4} \in \mathrm{C}$ satisfy $\exists \mathrm{i}:\left\{\mathrm{x}_{1, \mathrm{i}}, \mathrm{x}_{2, i}\right\} \cap\left\{\mathrm{x}_{3, \mathrm{i}}, \mathrm{x}_{4, i}\right\}=\emptyset$.
If in addition $x_{1, i}=x_{2, i}$ and $x_{3, i}=x_{4, i}$, we say that $C$ has a restricted $(2,2)$ separating property

## Robust 2-IPP codes

## Theorem:

$$
\begin{aligned}
& \epsilon_{\text {crit }}^{*, D}(3,2)=\epsilon_{\text {crit }}^{*}(3,2)=2 / 9 \\
& \epsilon_{\text {crit }}^{D}(3,2)=\epsilon_{\text {crit }}(3,2)=2 / 27
\end{aligned}
$$

## Summary

1. Fingerprinting codes. Pirates are not restricted in their detectable coordinates (but follow the marking assumption).

Exact identification impossible.
Families of randomized codes; fingerprinting capacity.
2. Parent identifying codes. Pirates must follow their assigned keys in both detectable and undetectable coordinates.

Exact identification possible
3. Robust parent identifying codes. Pirates are not restricted in detectable coordinates or do not follow the marking assumption, or both.

Under some restrictions exact identification is still possible.
t-IPP codes with distance
Preprint: IACR eprint archive 2011/227
