21 Municipalities, 13 depots, 24167 demand points.

Let r be a given time radius.

What we need

The SPP

Preprocessing

Bidirection search

Concave hull

Moving car

Sources

A demand point is covered by a depot if the driving time from that depot to the demand point is less than r.

Typical questions:

- Which demand points are covered by at least one depot?
- Which demand points are covered by at least two depots?
- What is the minimum driving time to any demand point?
- What is the route from one location to another?
- How to draw the area covered from any depot?

Coverage

| | #demand points | % |
|----------------|----------------|--------|
| Total | 24,167 | 100.0% |
| Uncovered | 1,160 | 4.8% |
| Covered | 23,007 | 95.2% |
| Double covered | 13,999 | 57.9% |

Algorithm 1: DIJKSTRA $(\mathcal{G} = (\mathcal{V}, A), s)$ 1: $d_v \leftarrow \infty \forall v \in \mathcal{V} \setminus \{s\}, d_s \leftarrow 0, \mathcal{Q} \leftarrow \{s\}$ repeat 2: Select a pivot node $v \leftarrow \arg\min\{d_v | v \in Q\}$ 3. $\mathcal{Q} \leftarrow \mathcal{Q} - \{v\}$ 4. foreach $(v, w) \in \mathcal{A}$ do 5: if $d_{v} + c_{vw} < d_{w}$ then 6: $d_w \leftarrow d_v + c_{vw}$ 7: if $w \notin \mathcal{Q}$ then 8: $| \mathcal{Q} \leftarrow \mathcal{Q} \cup \{w\}$ 9: until $\mathcal{Q} = \emptyset$ 10:

Coverage

What we need

The SPP

Preprocessing Bidirectional search

Concave hu

Moving car

Sources

Determining the coverage of each demand point can be done by growing a partial shortest path tree from each depot. Since r is usually small, this takes only a small amount of time.

Driving times

The shortest driving time to each demand point can be calculated by an updated initialization step. All nodes v that represent a depot are initialized with a zero label $d_v \leftarrow 0$. Furthermore, we stop the algorithm as soon as all demand points are chosen as a pivot node.

Quarter reduction (find the largest biconnected part)

Add shortcuts for 'degree 2 paths'

 v_1

Core nodes

v

A node that is not a 'quarter-node' and not a 'degree 2 node' is a *core* node.

w

Partitioning of the node set $\ensuremath{\mathcal{V}}$

Let $\mathcal{V}^0 \subset \mathcal{V}$ be the set of core nodes. A partition $\mathcal{V}^0, \mathcal{V}^1, \ldots \mathcal{V}^K$ of \mathcal{V} is determined, where $v, w \in \mathcal{V}^k (1 \le k \le K)$ if and only if there exists a path from v to w that contains only non-core nodes.

Guided search A*

A heuristic estimator h_v is provided. The pivot node is now selected according to $v \leftarrow \arg\min\{d_v + h_v | v \in Q\}$.

The SPP Preprocessing Bidirectional search

Concave ni

woving ca

Introduction What we need The SPP Preprocessing Bidirectional search Concave hull Moving car

Balanced approach

Forward search uses the estimate $h_v \leftarrow \frac{1}{2}\delta(v,t) - \frac{1}{2}\delta(s,v)$ Backward search uses the estimate $h_v \leftarrow \frac{1}{2}\delta(s,v) - \frac{1}{2}\delta(v,t)$

Let $\delta(v, w)$ be an underestimate for the distance from v to w.

As soon as both searches meet each other, a simple postprocessing step can be used to determine the shortest s-t distance.

Symmetric approach

Forward search uses the estimate $h_v \leftarrow \delta(v, t)$ Backward search uses the estimate $h_v \leftarrow \delta(s, v)$

A new stop condition is needed to be competitive with the balanced approach.

Scalar projections

Let \mathbf{x}_{v} be the coordinates of node v.

$$g_{v}^{s} = rac{(\mathbf{x}_{t} - \mathbf{x}_{s})^{\mathrm{T}}(\mathbf{x}_{u_{0}} - \mathbf{x}_{v})}{||\mathbf{x}_{t} - \mathbf{x}_{s}||_{2}}, \quad v \in \mathcal{V}$$

$$g_w^t = rac{(\mathbf{x}_s - \mathbf{x}_t)^{\mathrm{T}}(\mathbf{x}_{u_0} - \mathbf{x}_w)}{||\mathbf{x}_s - \mathbf{x}_t||_2}, \ \ w \in \mathcal{V}$$

Properties

Bidirectional search

$$g_{v}^{s} + g_{w}^{t} = \frac{(\mathbf{x}_{t} - \mathbf{x}_{s})^{\mathrm{T}}(\mathbf{x}_{w} - \mathbf{x}_{v})}{||\mathbf{x}_{t} - \mathbf{x}_{s}||_{2}}$$
$$g_{v}^{s} + g_{w}^{t} \le ||\mathbf{x}_{w} - \mathbf{x}_{v}||_{2}$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

We assume
$$c_{vw} \ge \alpha ||\mathbf{x}_w - \mathbf{x}_v||_2$$
, for some $\alpha > 0$.

As soon as a meeting node u_0 is settled from both sides we reject a new pivot node in the forward search if:

$$d_v^s + \alpha g_v^s \ge d_{u_0}^s$$

Moving co

Bidirectional search

Sources

Similarly, a pivot node in the backward search is rejected if:

$$d_v^t + \alpha g_v^t < d_{u_0}^t.$$

In our thesis, we present a proof that a node on a shortest path will not be rejected from both sides.

| | | Ensure : List <i>B</i> contains the edges of a concave hull | | |

Cond

When is it suitable to split an edge e?

- It depends on the length of *e* (global or local check)
- All points still remain inside the hull
- The hull has to be a simple polygon

Implementation

Place all points in a grid. In this way:

- The time needed for determining a new boundary node can be reduced.
- The maximum 'suitable' edge length can be determined locally.

Trajectory

A *trajectory* consists of a polyline together with its length and duration. The average speed on a traject is considered to be constant.

Route

A route is a sequence of trajectories.

Usage

If the route of a vehicle is known, the expected position of the vehicle at a certain time t can be determined.

- This can be used in a real-time environment to determine whether or not certain recalculations are necessary.
- In an off-line environment (e.g. a simulation) one has a more realistic position to determine statistics.
